About Public Health England

We work with national and local government, industry and the NHS to protect and improve the nation's health and support healthier choices. We address inequalities by focusing on removing barriers to good health.

We were established on 1 April 2013 to bring together public health specialists from more than 70 organisations into a single public health service.

About Biosafety Investigation Unit

The Biosafety Investigation Unit at Porton Down has been carrying out independent evaluations of infection control interventions in laboratories, health care, containment, workplace and domestic settings for over twenty years. Our expertise is in air and water microbiology applied to nosocomial, pharmaceutical and containment situations. We have developed and offer standard techniques for the determination of the efficacy of filters and air disinfection units, the performance of safety cabinets, sealed centrifuges rotors and air samplers. We are also able to assess liquid and gaseous disinfectants and the microbial air quality of healthcare facilities, workplaces and other environments.

The Biosafety Investigation Unit provides specialist bespoke research, testing and evaluation services for commercial customers that delivers independent analysis and reports. However as a public sector body we are not able to endorse any particular products or recommend them for use by the NHS or others.

Executive summary

The efficiencies of six filtered mouthpieces (V4 P/T Filtered 22mm Mouthpiece), supplied by CO Check, were determined against aerosols containing micro-organisms. Three filters were tested with aerosols containing bacterial spores (*Bacillus atrophaeus* NCTC 10073) and three were tested with aerosols containing viral particles (MS-2 coliphage, NCIMB 10108). The challenges were conducted at 11 litres min⁻¹ and a relative humidity of approximately 94%.

The results are summarised as follows:-

Filter	Test Organism	% Efficiency
F1	Bacillus atrophaeus	99.92
F2	Bacillus atrophaeus	99.97
F3	Bacillus atrophaeus	99.81
F1	MS-2 coliphage	99.41
F2	MS-2 coliphage	99.82
F3	MS-2 coliphage	99.79

Introduction

Contamination of respiratory apparatus during mechanical ventilation has been recognised since 1965 as a source of noscomial infections (1). Disposable filters placed between the patient and the ventilation system is designed to prevent such contamination. There is a need for a standard method to test the effectiveness of these filters against bacteria and viruses. A system has been developed at the Health Protection Agency, Porton Down (HPA) to test the efficiencies of many types of microbiological filters including breathing system filters. An apparatus, developed originally by Henderson and Druett (2, 3) to study experimental airborne infection, is used where a suspension of micro-organisms in aqueous solution is nebulised by a 3-jet Collison spray forming a fine aerosol containing viable micro-organisms. The generated aerosols are injected into an air stream flowing into a 77 cm long stainless steel tube of 5 cm internal diameter. The relative humidity of the air in the spray tube is controlled to a desired value and monitored using wet and dry bulb thermometers in the air stream. The efficiencies of the filters are calculated by determining the airborne concentration of viable micro-organisms upstream and downstream of the filter using suitable aerosol sampling techniques and microbial assay methods.

Because of the health hazards involved, it is unrealistic to evaluate these filters using human viruses. Fortunately, RNA-phages are of a similar size as the smallest human viruses and the efficiencies of the filters for removing human viruses form air streams can be gauged by measuring the penetration of aerosolized coliphage through the filter. MS-2 phage is an unenveloped single stranded RNA coliphage, 23 nm in diameter with a molecular weight of 3.6 x 10⁶ Daltons. MS-2 coliphage sprayed from the supernatant of centrifuged spent bacterial lysate are known to remain infectious at the conditions tested here (4). By spraying this suspension from a Collison nebuliser, the airborne coliphage are carried in droplets, which are much larger than the infectious particles, consisting mostly of bacterial lysate and media constituents.

The choice of bacterial strains to challenge and test these filters is based on a nonpathogenic model providing the highest possible challenge concentration of viable microorganisms to allow a fully quantitative assessment of the filters to be made. To do this, spores of *Bacillus atrophaeus* were used as the bacterial model because they are known to survive the stresses caused by aerosolisation. The spores were washed thoroughly and finally suspended in distilled water before nebulisation. During nebulisation the water is rapidly evaporated from the droplets formed (even at high relative humidities) so that monodispersed aerosols of viable spores actually challenge the filter in this system (5).

Materials and Method

Test organisms

Bacillus atrophaeus (NCTC 10073)

The *B. atrophaeus* spores (4.38 x 10⁹ colony forming units (cfu) per ml) which had been thoroughly washed in distilled water were suspended in distilled water. The suspension was prepared from batches previously prepared by the HPA Production Division (6).

MS-2 coliphage (NCIMB 10108)

A vial of MS-2 phage (NCIMB 10108) was obtained from the National Collection of Industrial and Bacteria, Torry Research Station, Aberdeen. A stock suspension of coliphage was prepared by inoculating 0.1 ml of a 10¹¹ plaque forming unit (pfu) per ml coliphage suspension into 500 ml nutrient broth containing 1 x 10⁸ Escherichia coli (NCIMB 9481) during the logarithmic growth phase. The suspension was acrated by shaking at 37°C. The bacterial cells lysed within 30 minutes and the suspension was centrifuged to remove the cell debris. The supernatant was transferred to a fresh flask and 10 drops of chloroform were added to kill any contaminating bacteria. This was used as the stock suspension of MS-2.

A high-titre suspension of MS-2 for challenging the filtered mouthpieces was prepared as follows:-

The *E. coli* 9481 host was inoculated on a fresh TSA plate, which was incubated at 37±2°C for 19 - 20 hr. The *E. coli* was sub-cultured from this plate by a 10 µl loop to 60 ml sterile Tryptone Soya broth (TSB) in a 500 ml flask. After mixing thoroughly the flask was placed in a shaking incubator (120 rpm) for 150 mins at 37 ±2°C. The suspension of coliphage was then prepared by inoculating a total of 4 x 10¹¹ plaque forming unit (pfu) coliphage suspension into the 500 ml flask containing the 100 ml TSB. The suspension was then aerated by shaking at 37 ±2°C for a further 3 hours. The suspension was centrifuged twice at 2,000g for 20 minutes each to remove the cell debris. The supernatant

was transferred to a fresh flask. The concentration of phage was 2.98×10^{12} pfu/ml. This was diluted to 2.98×10^{11} pfu/ml for use as the challenge test suspension. The phage assay is described later

Filters

Six filtered mouthpieces (V4 P/T Filtered 22mm Mouthpiece), supplied by CO Check ready to test (see figure 1).

Figure 1.

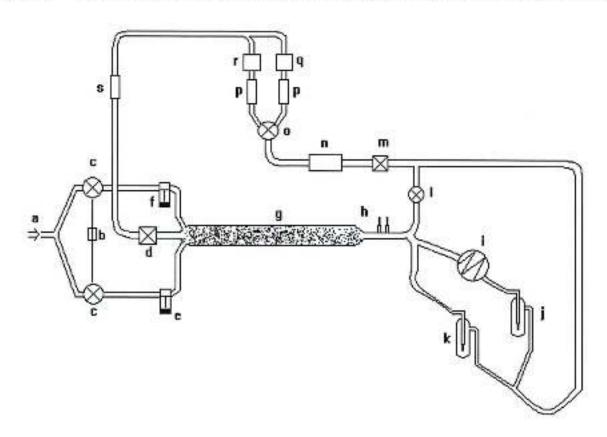

Challenging filters with microbial aerosols

The Henderson apparatus (Figure 2) was designed to deliver a high challenge concentration of micro-organism in aerosol at a high humidity of approximately 94% (measured by a wet and dry thermometer) (7) at 11 litres per minute.

The apparatus consisted of the following essential parts:-

- Two 3-jet Collison sprays (8), one containing 30 ml distilled water and one containing the microbial suspension. The Collison sprays were arranged so they could be operated alternatively to nebulise their contents at a pressure of 180 KPa into the spray tube
- Stainless steel spray tube 77 cm length and 5 cm diameter to allow mixing and conditioning of the aerosols generated from the Collison with a supply of clean filtered humidified air at 60 litres per minute.

- r Drier
- s Flowmeter

- Wet and dry thermometers downwind of the spray tube to determine the relative humidity.
- Suitable sterile silicone tubing connectors and tapers to allow insertion of the cartridge filter and housing to be tested in the system.
- Five 11 I/min Porton All-glass impingers (9) incorporating critical orifices to control the flow of sampled air. Each impinger contained 10 ml buffer solution (Phosphate buffer containing manucol and antifoam [PBMA]) and was connected to a vacuum pump. The impingers were operated in parallel at 11 litres per minute for the filters.
- The filters were inserted in the apparatus and the Collison spray containing the
 microbial suspension was activated. The air was sampled for three minutes by the
 impingers. The collecting fluid was removed from the impingers and assayed for
 microbes as described below.

Assay of B. atrophaeus in collecting fluids

The collecting fluids from two impingers linked to the spray tube (i.e. without filtered mouthpiece) was suitably diluted in PBMA. The number of spores was determined in a 10⁴ fold diluted fluid by spreading 0.1 ml on duplicate Tryptone Soya agar (TSA) plates. The TSA plates were incubated at 37°C for 24 hours and any orange colonies were counted. The neat, 10⁻¹, 10⁻² and 10⁻³ dilution of the collecting fluid from the impingers placed behind the filtered mouthpieces was also spread (0.1 ml) on duplicate TSA plates. These TSA plates were incubated at 37°C for 24 hours and any distinctive orange colonies were counted.

Assay of MS-2 coliphage in collecting fluids

A fresh TSA plate was inoculated with Escherichia coli NCIMB 9481 from a stock plate previously stored at $4 \pm 2^{\circ}$ C. This plate was incubated at $37 \pm 2^{\circ}$ C for 19 - 20 hrs. The E. coli 9481 was subcultured by transferring a 10 μ l loopful from the plate to 10 ml sterile nutrient broth in a glass universal bottle. After mixing, the universal bottle was incubated at

 $37 \pm 2^{\circ}\text{C}$ for 260 minutes before use. Meanwhile, stoppered bottles containing 3 ml volumes of soft phage agar were heated for at least 90 minutes at 90 to 100°C and then stored at $60 \pm 2^{\circ}\text{C}$ until required. These bottles were then cooled to 45°C before use. The suitably diluted MS-2 suspension ($100 \, \mu\text{l}$) was added to the soft agar followed immediately by 3 drops of the *E. coli* 9481 suspension using a 50 D ($20 \, \mu\text{l}$ per drop) Pasteur pipette. After mixing, it was poured immediately on a Tryptone soya broth agar (TSBA) plate. Duplicate samples were carried out (the dilution selected should give 30 to 100 plaque forming units (pfu) per plate). The plates were incubated at $37 \pm 2^{\circ}\text{C}$ overnight. The clear plaques were counted.

Determination of effectiveness of the filter

The effectiveness of the filter is expressed in the following way:-

Percentage efficiency. This is defined as follows:-

cfu/pfu collected without filter in place – cfu/pfu with filter in place X 100
Cfu/pfu collected without filter in place
